Abstract

With fast pace of development of artificial intelligence (AI) technologies, healthcare system has been under huge changes in giving medical cares, specially in nursery field. AI has an important role in improvement of patient care quality and reducing nurses workload with using clinical decision making assistant systems and checking health data and electronic folders. The purpose of this paper is reviewing the role of taking care of a patient based on AI in nursery field, with focus on improving clinical results and reducing workload and stress of nurses. This research shows that although AI can automate many repetitive and administrative work chores and improve the quality of clinical decision makings, but has challenges like the need to teach, ethical concerns, and increasing chance of technology based stress based on reviewing existing research papers.

Research evidence shows that AI-based tools, including clinical decision support systems, intelligent vital signs monitoring, and electronic health records, can reduce nurses' workload by automating repetitive and time-consuming tasks and allow them to focus more on direct patient care (Alnawafleh, 2024; Ayoola et al., 2024; ElArab et al., 2025; Rony et al., 2024; Ahmed et al., 2025; Dailah et al., 2024; Yuan et al., 2025; Liao et al., 2024; Hassan et al., 2024; Batisa, 2025; Hassanein et al., 2025; Khan et al., 2025; Al Khatib & Ndiaye, 2025; Kazmi, 2025; Nematollahi Maleki et al., 2025; Tong et al., 2023; Jeong et al., 2025; Chu, 2024; Ventura-Silva et al., 2024; Rony et al., 2024). This reduction in workload not only increases the professional efficiency of nurses, but also plays an important role in reducing job fatigue and preventing professional burnout (Yuan et al., 2025; Batisa, 2025; Jeong et al., 2025; Chu, 2024).

From a clinical outcomes perspective, studies show that the use of AI-based systems is associated with increased accuracy of clinical decision-making, early detection of critical situations, and reduction of human errors. These capabilities are especially important in stressful environments

such as intensive care units and can significantly improve patient safety and the quality of nursing care (Yuan et al., 2025; Alnawafleh, 2024).

However, the findings suggest that the impact of AI on the nursing profession is not always one-sided and positive. Some nurses have reported increased stress from learning new technologies, dependence on digital systems, and concerns related to technical disruptions and liability. This phenomenon, known as "technological stress", can have negative effects on nurses' work experience in the absence of adequate training and user-centered design of systems (Ramadan et al., 2024).

Overall, the results of this article show that artificial intelligence, if implemented in a principled, human-centered manner, and accompanied by training and organizational support, can serve as a complementary tool in the nursing profession and lead to improved patient outcomes and reduced nurses' workload. However, maintaining the role of professional judgement, human connection, and ethical considerations in the patient care process is a fundamental condition for the safe and effective use of this new technology (Alnawafleh, 2024).

Keywords: Artificial Intelligence (AI), AI-assisted Patient Care, Clinical Decision Support Systems, Nursing Workload, Patient Outcomes, Healthcare Technology, Critical Care Nursing

1. Introduction

The nursing profession is one of the main pillars of the health system, and nurses play a key role in providing direct care, monitoring patients, and implementing treatment decisions. However, the increasing complexity of clinical care, shortage of human resources, and high volume of

documentation have led to increased workload and job stress for nurses, especially in intensive care units (Alnawafleh, 2024).

In recent years, artificial intelligence has been introduced as a new solution to improve the quality of care and reduce the workload of nurses. Intelligent systems are able to analyze large volumes of clinical data, provide early warnings, and support clinical decision-making. Despite these benefits, the true impact of AI on nurses' work experience and patient outcomes require rigorous scientific investigation. This article attempts to examine the opportunities and challenges of this technology, focusing on patient care with the help of artificial intelligence in the nursing profession.

Despite the potential benefits of AI, scientific evidence suggest that the impact of this technology on the nursing profession is not one-dimensional. Along with improving the efficiency and quality of care, challenges such as the need for specialized training, stress from adapting to new technologies, ethical concerns related to data privacy, and the possibility of over-reliance on intelligent systems have also been raised. Therefore, a comprehensive and empirically evidence-based study of the actual impact of artificial intelligence on nurses' workload, job stress, and patient care outcomes seems necessary.

Accordingly, this article, focusing on patient care with the help of artificial intelligence in the nursing profession, attempts to examine the role of this technology in improving treatment outcomes and reducing nurses' workload by reviewing the theoretical foundations and existing empirical evidence. The study also identifies the opportunities and challenges facing the use of artificial intelligence in nursing and emphasizes the importance of a human-centered and ethical approach in implementing this technology.

2 Literature Review

Theoretical and experimental evidences show that between nurses workload, level of work stress, and quality of patient care there's a meaningful relationship. Previous studies emphasize that heavy workload and psychological stress can cause lower care quality and higher job exhaustion. Based on experimental evidences, using tools based on AI, like clinical decision making assistant systems and electronical smart health files, can reduce a part of time consuming chores of nurses and increase accuracy of cares (Alnawafleh, 2024). However, some evidences show that with lack of proper teaching and assistance, smart technologies may themselves become a source of job stress.

2.1 Theoretical foundations of the application of artificial intelligence in the nursing profession

Artificial intelligence refers to a set of technologies that are capable of simulating human cognitive processes such as learning, reasoning, and decision-making. In the health field, artificial intelligence is mainly used in the form of clinical decision support systems, health data analysis, patient condition prediction, and clinical process automation. From a theoretical perspective, the use of AI in nursing is aligned with theories of workload management, patient safety, and evidence-based care.

According to cognitive load theory, increasing information volume and simultaneous tasks can lead to reduced decision-making accuracy and increased human errors. By filtering out unnecessary data and providing relevant information, AI can reduce nurses' cognitive load and increase their focus on direct patient care (Ayoola et al., 2024; Rony et al., 2024).

2.2 Artificial intelligence and nurse workload management

One of the fundamental challenges of the nursing profession is the high volume of administrative and documentation tasks that consume a significant amount of nurses' time. Theoretical evidence suggests that automating these tasks through artificial intelligence-based systems can improve clinical workflow and increase nurses' efficiency.

Empirical studies have shown that intelligent data recording, vital sign monitoring, and medication reminder systems reduce the time spent on indirect care tasks and provide more opportunity for nurse-patient interaction (Alnawafleh, 2024). These findings confirm that AI can serve as an effective tool in managing nurses' workload.

2.3 Empirical evidence on job stress and burnout in nurses

Burnout is a common consequence of high workload in the nursing profession and is associated with reduced quality of care and increased clinical errors. Empirical studies show that reducing workload through smart technologies can lead to reduced job stress and improved mental health of nurses (Alnawafleh, 2024).

At the same time, theoretical and empirical evidence points to the phenomenon of "technological stress" resulting from exposure to complex systems, changing work patterns, and the need to learn new skills. Research emphasizes that without adequate training and user-centered design, AI technologies may increase nurses' psychological strain rather than reduce stress (Hassan et al., 2024; Tong et al., 2023; Ramadan et al., 2024).

2.4 The role of artificial intelligence in improving the quality of care and patient safety

From a theoretical perspective, the quality of nursing care depends on accurate decision-making, timely response, and effective interaction with the patient. By analyzing clinical data and identifying hidden patterns, AI can provide early warnings about the deterioration of a patient's

condition and prevent serious complications (Ahmed et al., 2025; Dailah et al., 2024; Liao et al., 2024; Batisa, 2025).

3 Methodology

This research is a analytical review study with purpose of reviewing the role of AI in patient care in nursery field and the impact of it in workload and patients clinical outcomes. In this research, data has gathered secondary and with reviewing existing scientifical research papers.

3.1 Data Resources

The main using resource in this paper, is the research done by Alnawafleh (2024) that is about the effect of using AI in workload and level of nurses stress in special care sections. This study was conducted in a real clinical setting and data were collected through structured questionnaires. The main focus of the research was on nurses working in ICUs, as these environments impose the highest workload on nurses in terms of workload, decision-making complexity, and sensitivity of care (Alnawafleh, 2024).

Choosing this statistical population allows for a more detailed examination of the role of artificial intelligence in situations where nurses' workload and job stress are at their highest levels (Alnawafleh, 2024).

The data obtained from this study have been used as the main basis for analysis in this article, and its findings have been compared and interpreted with theoretical and empirical evidence from other related studies in the field of artificial intelligence and nursing. This research's reliance on empirical data from a real intensive care environment increases the validity of the results and their applicability in analyzing the impact of artificial intelligence on the nursing profession.

3.2 Research sample society

In the reference study, the statistical population included nurses working in hospital intensive care units, and the research sample included 150 nurses with varying levels of work experience and experience using AI-based systems. The sample was selected on a convenience in the ICU and familiarity with digital health tools were considered.

3.3 Data collection tools

A standard questionnaire was used to collect data, which consisted of three main sections:

1. Demographic information (age, gender, work experience, education level)
2. The use of artificial intelligence-based tools in nursing care
3. Assessing nurses' workload and job stress levels

This questionnaire was designed to measure nurses' perceptions of the impact of artificial intelligence on work processes and the quality of patient care, and its validity and reliability have been confirmed in the original study (Alnawafleh, 2024).

3.4 Data analysis method

In the reference study, the collected data were examined using descriptive and analytical statistical methods. Indicators such as mean, standard deviation, and frequency distribution were used to describe the variables, and the relationships between the use of artificial intelligence, workload, and stress levels of nurses were analyzed. The results obtained are the basis for the analysis and interpretation of the findings of this article.

3.5 Ethical considerations

The reference study was conducted in compliance with the principles of research ethics. The participation of nurses was voluntary and the confidentiality of their personal information was guaranteed. Also, the data were used solely for research purposes (Alnawafleh, 2024).

3.6 Methodological limitations

Limitations of this method include the reliance of the results on nurses' self-reported data and the study being limited to a specific clinical settings. Therefore, generalization of the results to other healthcare settings should be done with caution. However, the findings provide valuable insight into the role of AI in reducing workload and improving nursing care.

4 Research and Development

4.1 AI effect on nurses workload

Research findings show that using AI based technologies can have an effective role in reducing nurses workload. Smart systems can reduce spent time on not caring chores like clinical documenting, monitoring vital signs, and managing patient data and create the ability for nurses more focus on direct care of patient (Alnawafleh, 2024; Liao et al., 2024).

Reduction of workload not only leads to increasing nurses efficiency, but also is important from patient security too; Because less tiredness leads to less clinical errors.

From a cognitive perspective, AI reduces decision-making burden by providing clinical alerts, analyzing complex data, and prioritizing patients. This is especially important in situations where nurses are responsible for caring for multiple critically ill patients at the same time. Studies show that reducing cognitive load can increase the accuracy of clinical performance and prevent burnout (Hassanein et al., 2025; Khan et al., 2025).

However, findings suggest that workload reductions from AI are contingent on proper implementation of the technology. Some studies suggest that in the early stages of deploying intelligent systems, nurses may experience a temporary increase in workload due to the need to learn new technology. This increase is usually linked to inadequate training, poor user interface design, and lack of organizational support (Kazmi, 2025; Tong et al., 2023; Alnawafleh, 2024). Therefore, the positive impact of AI on nurses' workload will be sustainable when the technology is implemented in a gradual, user-centered manner, and tailored to the real needs of the clinical environment.

Overall, the findings suggest that AI can serve as an effective tool for managing nurses' workload and, by reducing physical and cognitive strain, improve the quality of care and increase job satisfaction. However, realizing these benefits requires simultaneous attention to human, educational, and organizational factors alongside technological development.

4.2 AI and nurses job stress

The results of research shows that AI effect on nurses job stress has two sides. In one hand, clinical decision making assistant systems reduce the psychological stressed from vital decision makings and cause more control feeling on patient condition with giving exact and on time warnings.

On the other hand, some research show that adapting to new technologies needs learning digital skills and the stress of technical errors can increase technological stress (ElArab et al., 2025; Ahmed et al., 2025; Batisa, 2025; Chu, 2024). These findings suggest that the ultimate impact of AI on nurses' stress depends on the level of training, organizational support, and user-centered design of the systems.

However, the available evidence suggests that the positive impact of AI on job stress is not always guaranteed. Some studies point to a phenomenon called technostress, which arises as a result of the use of complex technologies, the need for continuous learning, changes in work patterns, and dependence on digital systems (Dailah et al., 2024; Yuan et al., 2025; Hassan & El-Ashry, 2024; Hassanein et al., 2025; Jeong et al., 2025). Nurses may experience increased stress in the early stages of implementing AI technologies, especially if they have not received adequate training or the systems are not user-centered in design.

In addition, concerns about technical disruptions, system errors, and liability if AI systems make incorrect decisions can lead to increased psychological stress for nurses.

4.3 Improving the quality of care and clinical outcome of patients

Research evidence suggests that the use of AI is associated with improved quality of patient care and improved clinical outcomes. AI-based systems are able to identify abnormal patterns in clinical data and provide early warnings, which leads to faster detection of critical situations and reduced human errors (Ventura-Silva et al., 2024; Ramadan et al., 2024; Ayoola et al., 2024; Rony et al., 2024; Batisa, 2025; Khan et al., 2025; Alnawafleh 2024).

In addition, reducing nurse fatigue and increasing the accuracy of clinical decision-making indirectly improves nurse-patient satisfaction with the care received (Kazmi, 2025; Ventura-Silva, 2024; Dailah et al., 2024; Yuan et al., 2025; Al Khatib & Ndiaye, 2025; Nematollahi Maleki, 2025; Jeong et al., 2025).

4.4 The role of clinical decision support systems

Artifical intelligence-based clinical decision support systems are recognized as one of the most important applications of AI in nursing. These systems help nurses make complex decisions by analyzing patient data and providing evidence-based recommendations.

Research shows that these systems are particularly useful for less experienced nurses and can increase accuracy and professional confidence, provided that they do not replace human clinical judgement (Ventura-Silva et al., 2024; Rony et al., 2024; Dailah et al., 2024; Liao et al., 2024; Al Khatib & Ndiaye, 2025; Alnawafleh, 2024; ElArab et al., 2025; Ahmed et al., 2025).

4.5 Ethical and professional challenges

Despite its numerous benefits, the use of AI in nursing is associated with ethical and professional challenges. Issues related to patient data confidentiality, liability in the event of system errors, and reduced human interaction are among the concerns raised in various studies (Dailah et al., 2024; Liao et al., 2024; Batista, 2025; Tong et al., 2023; Chu, 2024; Ramadan et al., 2024; Rony et al., 2024; Khan et al., 2025; Kazmi, 2025).

Research emphasize that for safe and effective use of AI in nursery, building ethical rules, continuous teaching, and active contribution of nurses in design and application of the systems is necessary.

These results suggest that successful integration of AI into nursing requires ethical frameworks, clear guidelines, and ongoing professional education.

4.6 Comparative analysis and discussion summary

Overall, findings from the reviewed articles suggest that AI can:

- Reduce nurse workload.

- Increase the quality of patient care.
- Improve safety and treatment outcomes.

5. Conclusion

The findings of this paper show that AI as one of the most important new coming technologies in health field, has a significant potential for creating changes in nursery field and increasing the quality of patient care. Findings show that using AI based tools, specially clinical decision making assistant systems and patient care smart systems, can lead to decreasing nurses workload and increasing effectivity of care processes. Reduction of repetitive and administrative tasks, gives the nurses the ability to spend more time and energy on direct care and human interactions.

In addition to reducing workload, evidences show that AI can have a critical role in improving clinical decision making. Accurate and rapid analysis of clinical data by intelligent systems enables early detection of critical situations, reduces human error, and increases patient safety. This is especially important in high-stress environments such as intensive care units, where quick and accurate decision-making can have a direct impact on patient outcomes.

However, the findings show that the impact of AI on nurses' work experience is not always one-sided and entirely positive. Alongside significant benefits, there are also challenges such as technological stress, the need for ongoing training, ethical concerns and over-reliance on technology. These challenges show that the success of AI in the nursing profession does not depend solely on technological advancements, but also on how it is implemented, the user-centered design of systems, and the level of organizational support.

From a professional ethics perspective, maintaining the confidentiality of patient data, transparency in AI-based decision-making, and the continuation of the human role of nurses in the

care process are considered basic requirements for using this technology. Artificial Intelligence should not replace the professional judgement and clinical experience of nurses, but should act as a complementary tool alongside human knowledge, making the care process safer and more efficient.

Ultimately, it can be concluded that the successful integration of AI into the nursing profession requires a human-centered, gradual, and education-based approach. Policymakers and health system managers should provide the basis for the effective utilization of this technology by investing in nurse training, developing ethical frameworks, and actively participating in the design and implementation of smart systems.
